Electrical Characteristics ($V_{CC} = 3.0\text{V}$ to 3.6V , $T_A = -40^\circ\text{C}$ to $+85^\circ\text{C}$)

Parameters	Description	Test Conditions ⁽¹⁾	Com.		Units
			Min.	Max.	
t_{PLH}	Propagation Delay A_X to B_X ^(2,3)	$C_L = 50\text{pF}$, $R_L = 500\Omega$		250	ps
t_{EN}	Bus Enable		1	4.5	
t_{DIS}	Bus Disable		1	5.0	
t_M	Make-before-break time		0	2	

Notes:

- See test circuit and waveforms.
- This parameter is guaranteed but not tested on Propagation Delays.
- The bus switch contributes no propagational delay other than the RC delay of the On-Resistance of the switch and the load capacitance. The time constant for the switch alone is of the order of 0.25ns for 50pF load. Since this time constant is much smaller than the rise/fall times of typical driving signals, it adds very little propagational delay to the system. Propagational delay of the bus switch when used in a system is determined by the driving circuit on the driving side of the switch and its interaction with the load on the driven side.

Switch Position

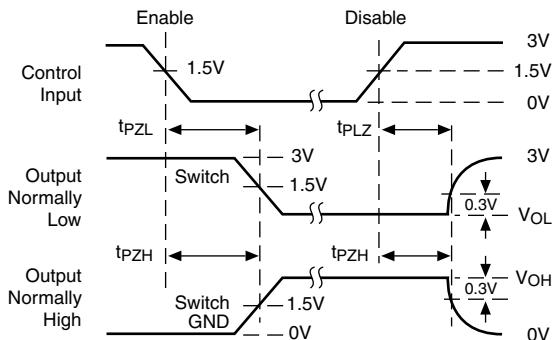

Test	Switch
Disable LOW	6V
Enable LOW	6V
Disable HIGH	GND
Enable HIGH	GND
t_{PD}	Open

Definitions:

C_L = Load capacitance (includes jig and probe capacitance)

R_T = Termination resistance (should be equal to Z_{OUT} of the pulse generator)

Enable and Disable Timing

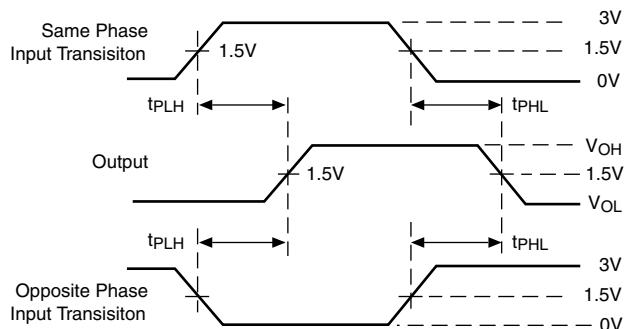

1. Input Control Enable = Low; Input Control Disable = High

2. Pulse Generator for all pulses:

Rate ≤ 1.0 MHz; $Z_{OUT} \leq 50\Omega$; $t_F, t_R \leq 2.5$ ns

Applications Information

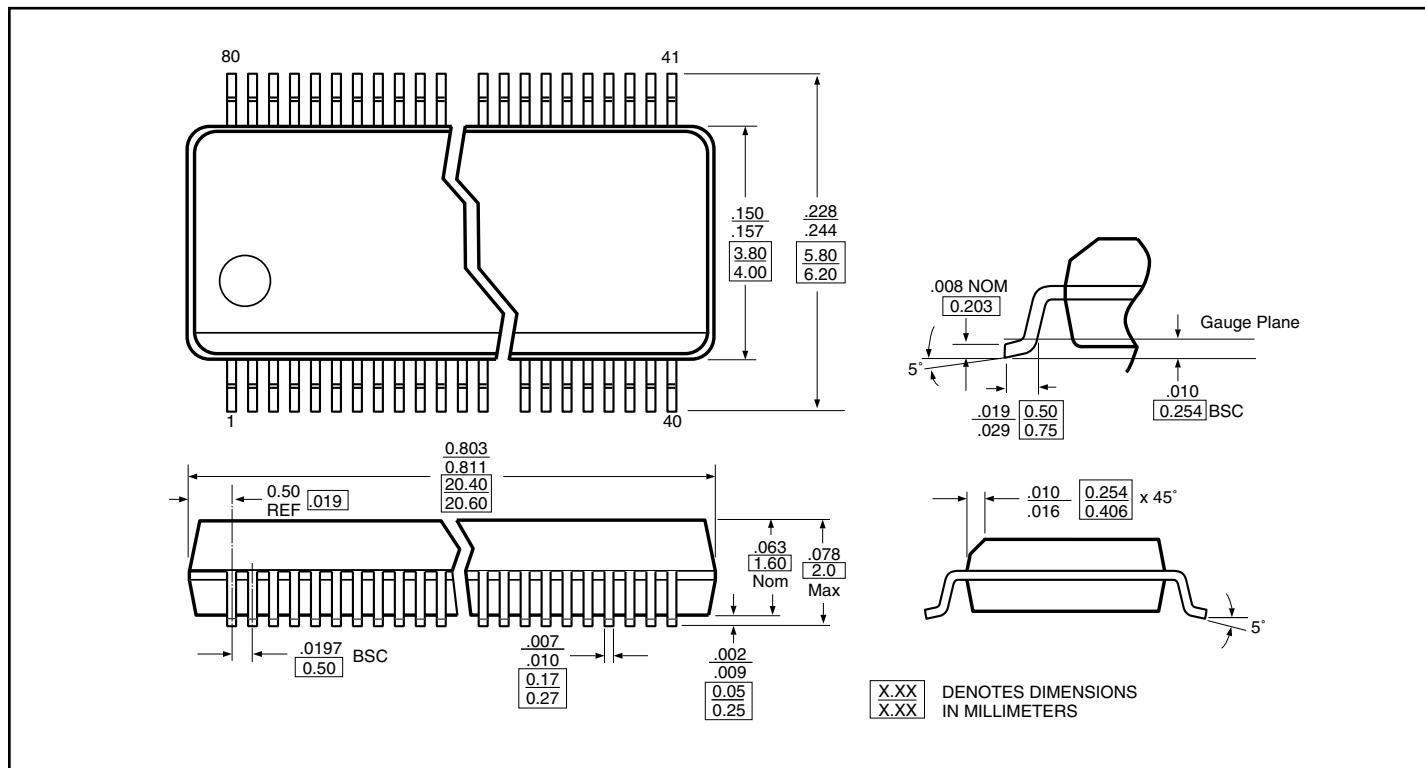

Logic Inputs

Logic control inputs can be driven up to +5.5V regardless of the supply voltage. For example, given a 5.0V supply, the control or select pins may be driven low to 0V and high to 5.5V. Driving the control or select pins Rail-toRail® minimizes power consumption.

Power-Supply Sequencing and Hot Plug Information

Proper power-supply sequencing is recommended for all CMOS devices. Always apply V_{CC} and GND before applying signals to the input/output or control pins.
